What's wrong with running Linux / UNIX shutdown command on a network?

Posted by [Vivek Gite](#) <vivek@nixcraft.com>

Q. I was reading some document online and come across statement like -- it is a bad idea to run halt / 'shutdown -h now' command over ssh/telnet session. What's wrong with running shutdown on a network?

The word "UNIX" is written in a large, bold, red, serif font.

A. shutdown command arranges for the system to be brought down in a safe way. All logged-in users are notified that the system is going down. In most cases system will also loss power and entirely shutdown. There will be no network access.

[1]

If you run this command remotely you will NOT able to turn on server until and unless you have some sort of remote reboot or power on/off capabilities for your server.
